Discriminator

Assume that  $g : \mathbb{N} \to \mathbb{N}$  is **injective** mapping. Let:

$$D_g(n) := \min\{m \in \mathbb{N} : g(1), g(2), \dots, g(n) \text{ are distinct modulo } m\}.$$
 (1)

The function  $D_g$  is commonly called the discriminator of the function g, because it provides the least modulus which discriminates the successive values of the function g.

The problem first appears in the context of the computation of square roots of a long sequence of integers.

Arnold, Benkoski, and McCabe [1] defined, for a natural number n, the smallest natural number m such that  $1^2, 2^2, \ldots, n^2$  are all distinct modulo m.

In this case, the value  $D_{g}(n)$  for n > 4 is the smallest  $m \ge 2n$  such that m is a prime or twice a prime.

Bremser, Schumer, Washington [2] determined for each sufficiently large natural number, the smallest positive integer m such that  $1^j, 2^j, \ldots, n^j$  are all incongruent modulo m.

[1] L.K. Arnold, S.J. Benkoski and B.J. McCabe, The discriminator (a simple application of Bertrand's postulate). Amer. Math. Monthly (1985), 92, 275-277.

Lately, the discriminators of various types of functions were considered by Zieve [13], Sun [9], Moree and Zumalacárrequi [6], Haque and Shallit [4].

4 / 37

イロト イポト イヨト イヨト

There is also a slightly different definition of a discriminator in terms of cancellations algorithms.

Instead of (1) Browkin and Cao also considered an arbitrary function  $f:\mathbb{N}\times\mathbb{N}\to\mathbb{N}$  with the set

$$A_n = \{f(n_1, n_2) : n_1 + n_2 \le n; n_1, n_2 \in \mathbb{N}\}.$$

They cancel from  $\mathbb N$  all numbers from the set of divisors

$$D_n = \{ d \in \mathbb{N} : d | m \text{ for some } m \in A_n \},\$$

and define  $b_f(n)$  to be the least non-canceled number (see Browkin and Cao in the paper [3]).

<sup>[3]</sup> J. Browkin, H-Q. Cao, Modifications of the Eratosthenes sieve, Colloq. Math, 135, (2014), pp., 127, 138 - na and a sieve colloq.

# Example

lf

$$\begin{split} A_n &= \{ \left( n_1 + n_2 \right)^2 - n_2^2 : n_1 + n_2 \le n; \, n_1, n_2 \in \mathbb{N} \}. \\ D_n &= \{ d \in \mathbb{N} : \exists_{n_1, n_2 \in \mathbb{N}, \, n_1 + n_2 \le n} \ d | \left( n_1 + n_2 \right)^2 - n_2^2 \} \end{split}$$

and  $b_f(n)$  is the least number in the set  $\mathbb{N} \setminus D_n$  then

$A_1 = \emptyset$	
$D_1 = \emptyset$	$b_f(1)=1,$
$A_2 = \{3\}$	
$D_2 = \{1, 3\}$	$b_f(2)=2,$
$A_3 = \{3, 5, 8\}$	
$D_{3} = \{1, 2, 3, 4, 5, 8\}$	$b_f(3) = 6,$
$A_4 = \{3, 5, 7, 8, 12, 15\}$	
$D_4 = \{1, 2, 3, 4, 5, 6, 7, 8, 12, 15\}$	$b_f(4)=9,$
$A_{5} = \{3, 5, 7, 8, 9, 12, 15, 16, 21, 24\}$	
$D_{5} = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 12, 15, 16, 21, 24\}$	$b_f(5) = 10,$
$A_{6} = \{3, 5, 7, 8, 9, 11, 12, 15, 16, 20, 21, 24, 25, 27, 32, 35\}$	
$D_{6} = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 15, 16, 20, 21, 24, 27, 32, 35\}$	$b_f(6) = 13,$
$A_{7} = \{3, 5, 7, 8, 9, 11, 12, 13, 15, 16, 20, 21, 24, 25, 27, 32, 33, 35, 45, 48\}$	
$D_{7} = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 20, 21, 24, 25, 27, 32, 33, 35, 45, 48\}$	$b_f(7) = 14,$
•••	

Note that  $A_n = \{g(s) - g(r) : 1 \le r < s \le n\}$ , where  $g : \mathbb{N} \ni r \to r^2 \in \mathbb{N}$ . In this case  $f(n_1, n_2) = (n_1 + n_2)^2 - n_1^2$  and  $b_f(n)$  is equal to the discriminator  $D_{r^2}(n)$ .

Hence for n > 4 we get that  $b_f(n)$  is the smallest  $m \ge 2n$  such that m is a prime or twice a prime.

### Definition 2.1

Let  $f : \mathbb{N}^s \to \mathbb{N}$ . We define for a natural number *n*.

$$b_f(n) = \tag{2}$$

 $\min\{m \in \mathbb{N}: \neg(\exists_{n_1,n_2,\ldots,n_s \in \mathbb{N}} m | f(n_1,n_2,\ldots,n_s) \land n_1 + n_2 + \ldots + n_s \leq n)\}.$ 

#### or in other words:

For a given  $n \ge 1$ ,  $D_n$  is the set of all divisors of all numbers  $f(n_1, n_2, \ldots, n_s)$ , where  $n_1 + n_2 + \ldots + n_s \le n$ . The numbers in  $D_n$  are cancelled, so the numbers in  $\mathbb{N} \setminus D_n$  remain non-cancelled. For  $n \ge 1$  the least non canceled number we denote by  $b_f(n)$ .

## Remark 2.2

# Note that, for a natural number n, the set

$$\{m \in \mathbb{N}: \exists_{n_1,n_2,...,n_s \in \mathbb{N}} m | f(n_1,n_2,...,n_s) \land n_1 + n_2 + ... + n_s \leq n \}$$

is finite, thus

$$\{m \in \mathbb{N} : \neg (\exists_{n_1, n_2, \dots, n_s \in \mathbb{N}} m | f(n_1, n_2, \dots, n_s) \land n_1 + n_2 + \dots + n_s \le n)\}$$

is not empty. Therefore by minimum principle  $b_f(n)$  exists. We also have  $b_f(1) = 1$  if s > 1.

### Lemma 3.11

For a natural number m > 4 and an odd number  $j \ge 3$  the following statements are equivalent

- (i) For all  $a, b \in \mathbb{N}$  such that  $a + b \leq m 1$  we have  $m \not| a^j + b^j$ ,
- (ii)  $(j, \varphi(m)) = 1$  and m is square-free,
- (iii)  $x^j$  is a permutation polynomial of the finite ring  $\mathbb{Z}/m\mathbb{Z}$ .

#### Theorems

It follows from [2,p.32] that (ii) and (iii) are equivalent. Assume that (ii) holds. If there exist  $a, b \in \mathbb{N}$  such that  $a + b \leq m - 1$  and  $a^j + b^j \equiv 0 \pmod{m}$ , then  $a^j \equiv (m - b)^j \pmod{m}$  and  $1 \leq a < m - b \leq m - 1$ . We obtain a contradiction with (iii). Hence (ii) implies (i).

On the other hand assume that (i) holds. Then for all  $a, b \in \mathbb{N}$ ,  $1 \le a < b \le m-1$ we have following relations  $m_i^{\prime} a^j + (m-b)^j$  and  $m_i^{\prime} a^j - b^j$ . Hence  $1^j, 2^j, \ldots, (m-1)^j$  are distinct modulo m. We will show that m is square-free. Suppose the contrary, we put  $m = p^2 1 > 4$ , where  $l \in \mathbb{N}$  and p is a prime number. If we take

$$\mathbf{a} = \left\{ \begin{array}{ccc} pl-p & \text{if} & p=2, \ l>1 \\ pl & \text{if} & p\geq3, \ l\geq1 \end{array} \right. , \quad \mathbf{b} = \left\{ \begin{array}{ccc} p & \text{if} & p=2, \ l>1 \\ pl & \text{if} & p\geq3, \ l\geq1 \end{array} \right. ,$$

then  $a + b \leq m - 1$  and  $a^j + b^j \equiv 0 \pmod{m}$ , thus we get contradiction with (i). Consequently m is a square-free number. Therefore  $a^j \equiv 0 \pmod{m}$  implies  $a \equiv 0 \pmod{m}$ .

Thus  $0^j$ ,  $1^j$ , ...,  $(m-1)^j$  are distinct modulo m and (iii) holds, hence (ii) holds also.

э

### Proof.

The first inequality follows from the fact that if j is an odd integer then  $(n_1 + n_2)|n_1^j + n_2^j$ . Indeed, for a natural number  $2 \le h \le n$ , we take  $n_1 = 1$ ,  $n_2 = h - 1$ . Hence  $h|n_1^j + n_2^j$  and  $n_1 + n_2 = h \le n$ . Therefore h is canceled. Hence  $b_f(n) > n$ . For the proof of the second inequality assume that m > n, m is square-free number,  $(j, \varphi(m)) = 1$ , then by

lemma 3.11 for all  $n_1, n_2 \in \mathbb{N}$  such that  $n_1 + n_2 \leq n \leq m-1$  we have  $m_i n_1^i + n_2^i$ . Hence  $b_f(n) \leq m$  and theorem follows.

# Definition 3.13

For *j* odd, let  $B_j$  be the smallest integer such that for all  $n > B_j$  there exists a prime *p* with (j, p - 1) = 1 and  $p \in (n, \frac{3}{2}n)$ .

## Remark 3.14

By the Prime Number Theorem for arithmetic progressions there is always a prime  $p \equiv 2 \pmod{j}$  in  $(n, \frac{3}{2}n)$  for n sufficiently large, see [2].

[2] P. S. Bremser, P.D. Schumer, L.C. Washington, A note on the incongruence of consecutive integers to a fixed power, J. Number Theory (1990), 35, no. 1, 105-108.

Maciej Zakarczemny (PK)

# Definition 3.15

For j odd, let  $Q_j$  be the set of all square-free positive integers m such that  $(j, \varphi(m)) = 1$ .

## Lemma 3.16

For all  $n > B_j$  there exists a number  $q \in Q_j$  such that  $q \in (n, \frac{3}{2}n)$ .

# Proof.

By definition of  $B_j$  and  $Q_j$ .

Maciej Zakarczemny (PK)

・ 戸 ト ・ ヨ ト ・ ヨ ト

We fix some odd integer  $j \ge 3$ . For the function  $f : \mathbb{N}^2 \ni (n_1, n_2) \rightarrow n_1^{j} + n_2^{j} \in \mathbb{N}$  and for all  $n > B_j$  we have  $n < b_f(n) < \frac{3}{2}n$ .

Moreover, if  $n > \max\{3, B_i\}$  then  $b_f(n)$  is a square-free number.

Maciej Zakarczemny (PK)

September 11-13, 2017

- 4 ⊒ →

### Proof.

By lemma 3.16, if  $n > B_j$  we get

$$\min \{m: m > n, m \text{ square} - free, (j, \varphi(m)) = 1\} < \frac{3}{2}n.$$

Thus by theorem 3.12 we obtain  $n < b_f(n) < \frac{3}{2}n$ . By the straightforward verification for all odd  $j \ge 3$  we have

$$b_f(1) = 1, \ b_f(2) = 3, \ b_f(3) = 4, \ b_f(4) = 5, \ b_f(5) = 6.$$

We will show that if  $n > \max\{3, B_j\}$  then  $b_f(n)$  is a square-free number. Suppose the contrary  $b_f(n) = p^2 l > 7$ , where  $l \in \mathbb{N}$  and p is a prime number. If p = 2 then  $l \ge 2$  we put a = 2l - 2, b = 2 and get  $b_f(n)|2^j((l-1)^j + 1)$ , since j odd,  $j \ge 3$ . Hence  $a + b = 2l = \frac{1}{2}b_f(n) < \frac{1}{2}(1 + \frac{1}{2})n < n$  and  $b_f(n)|a^j + b^j$ , thus we get contradiction with definition of  $b_f(n)$ . If p > 2 then we put a = pl, b = pl and get  $b_f(n)|a^j + b^j$ , since  $j \ge 3$ . But  $a + b = 2pl = \frac{2}{n}b_f(n) < \frac{2}{n}(1 + \frac{1}{2})n \le n$ ,

If p > 2 then we put a = pl, b = pl and get  $b_f(n)|a^r + b^r$ , since  $j \ge 3$ . But  $a + b = 2pl = \frac{1}{p}b_f(n) < \frac{1}{p}(1 + \frac{1}{2})n \le n$ , thus we get contradiction with definition of  $b_f(n)$ .

# Conjecture 3.18

We fix some odd integer  $j \ge 3$ . For the function  $f : \mathbb{N}^2 \ni (n_1, n_2) \to n_1^{\ j} + n_2^{\ j} \in \mathbb{N}$ , if a natural number  $n \ge 4$  then  $b_f(n) = \min\{m : m > n, m \text{ square} - free, (j, \varphi(m)) = 1\}$ (3)

= min {m: m > n, polynomial  $x^j$  permutes elements of  $\mathbb{Z}/m\mathbb{Z}$  }.

### Remark 3.19

For proof of Conjecture 3.18 in the case j = 3, see Theorem 3.10. The author found that the equation (3) holds for  $j \in \{5, 7, 9, 11, 13\}$  and  $n \in \{4, 5, \ldots, 200\}$ .
